(57) **ABSTRACT**

An optical lithography system comprises a light source, a spatial light modulator, imaging optics and means for continuously moving a photosensitive substrate relative to the spatial light modulator. The spatial light modulator comprises at least one array of individually switchable elements. The spatial light modulator is continuously illuminated and an image of the spatial light modulator is continuously projected on the substrate; consequently, the image is constantly moving across the surface of the substrate. While the image is moving across the surface, elements of the spatial light modulator are switched such that a pixel on the surface of the substrate receives, in serial, doses of energy from multiple elements of the spatial light modulator, thus forming a latent image on the substrate surface. The imaging optics is configured to project a blurred image of the spatial light modulator on the substrate, enabling sub-pixel resolution feature edge placement.

CONTINUOUS DIRECT-WRITE OPTICAL LITHOGRAPHY

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a divisional of U.S. Non-Provisional Application Ser. No. 10/646,525 filed Aug. 21, 2003 now U.S. Pat. No. 7,167,296, which claims the benefit of U.S. Provisional Application No. 60/406,030 filed Aug. 24, 2002, incorporated in its entirety by reference herein.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to the field of optical lithography, and in particular to printing patterns on the following substrates: wafers; printed circuit boards; flat panel displays; masks; reticles; and plates used for the reproduction of magazines, newspapers and books.

2. Description of the Related Art

The semiconductor industry uses very expensive stepper tools for lithographic processing. Furthermore, very expensive reticles are used in this processing—the cost of the reticles is sufficient to make low volume production of chips (such as custom ASICs) prohibitively expensive. The semiconductor industry needs a lower cost lithography process. Furthermore, every time the lithography pattern changes, several days or more are required to produce a new reticle. The semiconductor industry needs a lithography process which can quickly accommodate pattern changes.

The printed circuit board (PCB) industry has similar problems with its lithography processes. Furthermore, the substrates used in the PCB industry undergo distortion during fabrication which limits the use of high resolution lithography processing to small area substrates and the use of steppers. A high resolution lithographic process is required for large PCB substrates in which the pattern can be quickly and economically adjusted to accommodate the distortions, where the distortions vary from one substrate to the next.

U.S. Pat. Nos. 5,330,878 5,523,193 5,482,818 and 5,672,464 to Nelson describe a method and apparatus for patterning a substrate. The apparatus uses a spatial light modulator (SLM), specifically the Texas Instruments deformable mirror device (DMD), in place of a reticle. The DMD is an array of individually controllable reflective elements. An image of the DMD is projected on the substrate by an imaging lens. Whether or not an individual element of the DMD reflects light into the imaging lens, such that it is projected on the substrate, is determined by computer; thus the pattern projected on the substrate is computer controlled and readily changed. Improvements are required to this approach in order to meet the high resolution and throughput requirements of both the semiconductor and PCB industries. Furthermore, advancements are available to reduce the cost of the apparatus, while increasing the throughput and meeting the high resolution requirements.

SUMMARY OF THE INVENTION

The present invention provides an apparatus and method for patterning photosensitive substrates. The apparatus includes a spatial light modulator (SLM), a light source for illuminating the SLM, imaging optics for projecting an image of the SLM on the substrate, and means for moving the image across the surface of the substrate. The SLM

controls the pattern of light which reaches the substrate. The SLM comprises at least one array of individually switchable elements—switchable between two or more states. The SLM can be either a diffractive or a transmissive device. The light source can be a continuous light source, such as an arc lamp, LED or continuous laser; quasi-continuous lasers can also be used when the laser pulsing frequency is much higher than the switching frequency of the elements of the SLM. The means for moving the image can be a stage on which either the SLM or the substrate is mounted. When the substrate is in the form of a flexible film or similar, it may be moved using a reel to reel mechanism. While the image is moving across the surface of the substrate, elements of the spatial light modulator are switched such that a pixel on the surface of the substrate receives, in serial, doses of energy from multiple elements of the spatial light modulator, thus forming a latent image on the substrate surface. The imaging optics can be telecentric.

In preferred embodiments the imaging optics is configured to project a blurred image of the spatial light modulator on the substrate, enabling sub-pixel resolution feature edge placement. The blurring can be implemented by: adjusting the focus of the imaging optics; adjusting the numerical aperture of the imaging optics; adding a diffuser between the SLM and the substrate; adding a microlens array between the SLM and the substrate; or a combination of the aforementioned.

In preferred embodiments the spatial light modulator is continuously illuminated, an image of the spatial light modulator is continuously projected on the substrate, and the image is continuously moved across the surface of the substrate.

In some embodiments the SLM comprises a multiplicity of area arrays. The corresponding imaging optics can be a single projection lens system, or a multiplicity of projection lens systems. In the case of the latter, the number of the area arrays is greater than the number of the projection lens systems, and the number of projection lens systems is preferably a submultiple of the number of area arrays. Furthermore, the multiplicity of area arrays can be arranged in a line, or they can be arranged in multiple lines where the placement of the arrays is staggered from one line to another. The latter may utilize more of the imaging field of the projection optics, and can also result in a more efficient exposure of the substrate—reducing the need for a serpentine motion of the projected image of the SLM across the substrate during exposure.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 is a schematic representation of an optical lithography tool with a movable substrate, in accordance with the invention.

FIG. 2 is a schematic representation of an optical lithography tool with a movable spatial light modulator, in accordance with the invention.

FIG. 3 is a schematic representation of an optical lithography tool with a flexible film substrate, in accordance with the invention.

FIG. 4 is a detailed schematic representation of a first embodiment of the optical lithography tool of FIG. 1, showing telecentric projection optics.

FIG. 5 is a detailed schematic representation of a second embodiment of the optical lithography tool of FIG. 1, showing a spatial light modulator with multiple area arrays and corresponding multiple sets of projection optics.

FIG. 6 is a detailed schematic representation of a third embodiment of the optical lithography tool of FIG. 1, showing a spatial light modulator with multiple area arrays and a single set of telecentric projection optics.

FIG. 7 is a diagrammatic cross-sectional view through part of a micro-mirror array in accordance with the invention, showing array elements in 'on' and 'off' positions.

FIG. 8 is a plan view of a substrate showing a serpentine path that can be followed by the projected image of a spatial light modulator in order to expose the entire substrate surface, in accordance with the invention.

FIG. 9 is a plan view of a substrate showing serpentine paths that can be followed by projected images from each of a multiplicity of area arrays that are used together to expose the entire substrate surface, in accordance with the invention.

FIG. 10 is a diagrammatic representation of the process of forming a latent image, in accordance with the invention.

FIG. 11 is a diagrammatic representation of the substrate array of FIG. 10.

FIG. 12 is a graph showing instantaneous light intensity distributions along the line segment AB on the substrate of FIG. 10, at equally spaced time intervals $T/10$, starting at T3.

FIG. 13 is a graph showing instantaneous light intensity distributions along the line segment AB on the substrate of FIG. 10, at equally spaced time intervals $T/10$, ending at T4.

FIG. 14 is a graph showing the integrated dose distribution along the line segment AB on the substrate of FIG. 10, due to light exposure between times T3 and T4.

FIG. 15 is a graph showing the total dose distribution along the line segment AB on the substrate of FIG. 10, due to light exposure between times T1 and T7.

FIG. 16 is a diagrammatic representation of the process of forming a latent image including a first example of edge shifting by one half of the projected width of a mirror, in accordance with the invention.

FIG. 17 is a diagrammatic representation of the process of forming a latent image including a second example of edge shifting by one half of the projected width of a mirror, in accordance with the invention.

FIG. 18 is a diagrammatic representation of the process of forming a latent image including an example of edge shifting by one quarter of the projected width of a mirror, in accordance with the invention.

FIG. 19 is a diagrammatic representation of the process of forming a latent image including an example of edge shifting by three quarters of the projected width of a mirror, in accordance with the invention.

FIG. 20 is a diagrammatic representation of the process of forming a latent image including an example of edge shifting in another direction by one quarter of the projected width of a mirror, in accordance with the invention.

FIG. 21 is a graph showing the integrated dose distributions along the line segment AB on the substrates of FIGS. 10, 16, 17, 18 and 19.

FIG. 22 is a further diagrammatic representation of the process of forming a latent image, in accordance with the invention.

FIG. 23 is a diagrammatic representation of the substrate array of FIG. 22.

FIG. 24 is a graph showing the integrated dose distributions along the line segments CD, EF, GH and IJ on the substrate of FIG. 22.

FIG. 25 is a diagrammatic representation of the process of forming a latent image including a further example of edge shifting, in accordance with the invention.

FIG. 26 is a diagrammatic representation of the substrate array of FIG. 25.

FIG. 27 is a graph showing the integrated dose distributions along the line segments KL, MN, OP, QR and ST on the substrate of FIG. 25.

FIG. 28 is a block diagram of an optical lithography system in accordance with the invention.

FIG. 29 is a plan view of an arrangement of multiple area arrays in accordance with an embodiment of the invention.

FIG. 30 is a schematic representation of another embodiment of the optical lithography tool of FIG. 4, showing a light switching mechanism 121 on the light path between the light source and the substrate.

FIG. 31 is a timing diagram of an optical lithography system with two spatial light modulators configured in serial on the light path, in accordance with the invention.

FIG. 32 is a diagrammatic representation of the process of forming a latent image using an optical lithography system with two spatial light modulators configured in serial on the light path, in accordance with the invention.

FIG. 33 is a timing diagram of an optical lithography system with a spatial light modulator and a light switching mechanism configured in serial on the light path, in accordance with the invention.

FIG. 34 is a schematic representation of an optical lithography tool with light optics configured to overlap projected images of two area arrays on the substrate surface, in accordance with the invention.

FIG. 35 is a timing diagram of the optical lithography system of FIG. 34.

DETAILED DESCRIPTION

With reference to FIG. 1, optical lithography tool 100, which is an embodiment of the invention suitable for patterning a substrate 140 mounted on a movable stage 150, is shown with a light source 110, a spatial light modulator (SLM) 120 and imaging optics 130. Coordinate axes 160 are shown with the z and y axes in the plane of the figure and the x axis perpendicular to the plane of the figure. The light path through the optical lithography tool is represented by rays 170. The light source 110 continuously illuminates the SLM 120. The light source may comprise an arc lamp, continuous laser (solid state or gas), light emitting diode (LED) or other type of continuous light source that has suitable spectral properties for exposure of the substrate 140. Furthermore, a light source such as a quasi-continuous laser (a laser which is pulsed at MHz frequencies), may be suitable as a light source for this invention—a critical criteria is that the pulsing frequency be much higher than the switching frequency for elements of the spatial light modulator (typically 10^4 Hz); in this case the illumination of the SLM by the light source is effectively continuous. The light source may also comprise optical components for increasing the intensity of illumination and to improve illumination uniformity. These may include an elliptical mirror, both round and cylindrical lenses, and light pipes or fly's eye lens arrays. SLM 120 is one or more area arrays (generally rectangular) of elements that act on the light beam from the light source. An image of the SLM is continuously projected onto the substrate by the imaging optics 130, which is also referred to as the projection optics. The elements can be individually switched between two or more states, under computer control, so as to control the light amplitude in the image. One embodiment of the invention includes an SLM which is an array of mirrors or diffractive elements that can switch incoming light rays between two or more angular

states. A digital micro-mirror device (DMD), currently available from Texas Instruments, is an example of a suitable mirror-array that can switch between two angular states. An example of a diffractive SLM is the Grating Light Valve (GLV) currently manufactured by Silicon Light Machines. Other embodiments of the invention include SLMs which are Liquid Crystal Display (LCD) devices. If the elements of the SLM are transmissive, rather than reflective, then the optics will need to be rearranged; such a rearrangement will be obvious to those skilled in the art. Imaging lens system **130** may contain both reflective and refractive elements, and is typically telecentric. Substrate **140** either includes a photosensitive layer, such as a photoresist coating, or is itself a photosensitive material, such as a sheet of photosensitive polyimide. The stage **150** may be of a roller-bearing or air-bearing design and may have height adjustment (in z-direction), tilt and rotation capabilities. These types of stages are well known and commonly used in lithography systems. For simplicity of illustration the substrate is assumed to be planar. However, the invention will also work with other substrate shapes, such as cylindrical or spherical, along with a rotary rather than a planar stage.

With reference to FIG. 2, optical lithography tool **200**, which is an embodiment of the invention suitable for patterning a static substrate **140**, is shown with a light source **110**, SLM **120**, a stage **250** on which the SLM is mounted, and projection optics **130**. The method of operation is the same as for optical lithography system **100**, described above, except that stage **250** moves SLM **120** during exposure while substrate **140** is stationary. Imaging lens system **130** and/or illumination source **110** can also be attached to the stage **250** and move with the SLM.

With reference to FIG. 3, optical lithography tool **300**, which is an embodiment of the invention suitable for patterning a flexible substrate **340**, is shown with a light source **110**, SLM **120**, a stage **250** on which the SLM is mounted, projection optics **130**, and rotatable, spaced apart, axially parallel film drums **342** and **344**. The photosensitive flexible film substrate **340** is wrapped around and tensioned between film drums **342** and **344** such that the film can be moved in the y direction (referenced to stationary coordinate system **160**). Two modes of exposure are possible. In the first mode, stage **250** moves the SLM at constant speed in the x direction while the substrate **340** is stationary. When an exposure pass is complete (for example, the edge of the substrate is reached), the film drums index the substrate forward in the y direction and the stage reverses direction for the next exposure pass. The result is a serpentine exposure path similar to path **850** shown in FIG. 8, and discussed in more detail below. In the second mode the roles of the stage and film drums are reversed. While the stage is stationary, the film drums move the substrate at constant speed in the y direction until the edge of the exposure region is reached. The stage then indexes the substrate forward in the x direction and the film drums reverse direction for the next exposure pass. Again, this results in a serpentine exposure path. Furthermore, if the width of the area to be exposed on the substrate is less than or equal to the width of the projected image of the SLM, then the stage can remain stationary, or be eliminated, and the film drums move the substrate at a constant speed, without the need to reverse direction. As in other embodiments, the projection optics may be carried on the stage.

Referring to FIGS. 4, 5 and 6, different embodiments of optical lithography tool **100** (see FIG. 1) are shown in detail.

FIG. 4 is a schematic of a continuous direct-write optical lithography system with an arc lamp and a telecentric

projection lens system. Continuous illumination from mercury arc lamp **410** is reflected from elliptical reflector **411**. Reflected light, as represented by light rays **170**, travels to a dichroic mirror **412**, which reflects wavelengths useful for exposure of the substrate **140** (for example 350 nm-450 nm) and is transparent to other wavelengths. Light not reflected from the dichroic mirror is absorbed in illumination beam dump **413**. Other types of lamps can be used, such as a Xenon arc lamp, depending on the exposure wavelengths and source brightness needed. A light pipe **415** is used to improve the illumination uniformity, but could be replaced with a fly's eye lens array. A light pipe lens system **414**, positioned before the light pipe **415**, is used to adjust the numerical aperture of the illumination system and to adjust the diameter of the light beam prior to entering the light pipe. Condenser lens system **416** captures light exiting from the light pipe and modifies the beam shape and angle to match the requirements of the SLM **120**. The condenser lens system contains an illumination aperture **417**. The light pipe lens system and condenser lens system are usually anamorphic and contain cylindrical lens elements. The continuous illumination mercury arc lamp, elliptical reflector, dichroic mirror, illumination beam dump, light pipe lens system, light pipe, condenser lens system and illumination aperture comprise an embodiment of illumination source **110**, as shown in FIG. 1. The SLM is one or more area arrays (generally rectangular) of small mirrors that can switch between two or more angular states under computer control. At least one of the angular states reflects light rays from the illumination source into a telecentric projection lens system **430** and at least one other angular state reflects light rays into an SLM beam dump **480**. A digital micro-mirror device (DMD), currently available from Texas Instruments, is an example of a suitable mirror-array that can switch between two angular states. Mirrors in the "on" state in the SLM are imaged on the substrate by the telecentric projection lens system. Light reflected from mirrors in the SLM in the "off" state travels to the SLM beam dump where it is absorbed. Further details of the operation of a SLM are provided below and in FIG. 7. The substrate either contains a photosensitive layer, such as a photoresist coating, or is itself a photosensitive material, such as a sheet of photosensitive polyimide. The substrate is attached to stage **150**, which moves continuously during exposure in straight-line segments in the x-y plane of stationary coordinate system **160**. The numerical aperture of the telecentric projection lens system is determined by a projection lens aperture **432**, which is optically conjugate to illumination aperture **417**. A double telecentric projection lens system is shown. However, a single telecentric or non-telecentric projection system will also work. A telecentric design is preferred because the magnification does not change with substrate height, which simplifies calibration of the lithography tool for each substrate. The telecentric projection lens system is a type of projection lens system **130**, as shown in FIG. 1. The stage can move in a plane x-y and also in the z direction of the stationary coordinate system **160**. The stage **150** can also have rotation and tilt capability; this may be required for proper substrate alignment (for example, when substrate flatness is an issue). Movement in the z direction will either focus or defocus the projected image on the substrate. A substrate height measuring system **450**, utilizing height detection medium **490**, can be used to determine the z position of the surface of the substrate **140**. The height measuring system can be optical, capacitance or air based. The preferred type is air. Focusing can also be accomplished by moving either the SLM or projection lens system in the z direction.

FIG. 5 is a schematic of a continuous direct-write optical lithography system with an arc lamp, an SLM with multiple area arrays, and multiple projection lens systems. The light source is arranged as described above for FIG. 4, except that a condenser lens system 516 and lens array 518 capture light exiting from light pipe 415, so as to modify the beam shape and angle to match the requirements of the individual SLM area arrays 520 through 524. The lens array maximizes the light intensity on the individual SLM area arrays; the lens array is configured to match the arrangement of the SLM area arrays, which may be arranged in a line, multiple lines (see FIG. 29), or some other two dimensional arrangement. While not an essential component, incorporation of the lens array is preferred. The lens array may comprise lenses arranged correspondingly with the SLM area arrays; alternatively, the lenses in the lens array may be replaced with one or more diffractive elements. Light pipe lens system 414 and condenser lens system 516 are usually anamorphic and contain cylindrical lens elements. The continuous illumination mercury arc lamp 410, elliptical reflector 411, dichroic mirror 412, illumination beam dump 413, light pipe lens system 414, light pipe 415, condenser lens system 516 and lens array 518 comprise a type of continuous illumination source 110 as in FIG. 1. Each individual SLM area array 520 through 524 is a rectangular array of small mirrors that can switch between two or more angular states under computer control. A digital micro-mirror device (DMD) currently available from Texas Instruments is an example of a suitable mirror-array that can switch between two angular states. Mirrors in the "on" state in SLM area array 520 are imaged on the substrate 140 by projection lens 530; likewise for SLM area arrays 521 through 524 and their corresponding projection lenses 531 through 534. Light reflected from mirrors in SLM area array 520 in the "off" state travels to SLM beam dump 480 where it is absorbed; likewise for SLM area arrays 521 through 524. Five each SLM area arrays (520 through 524), projection lenses (530 through 534) and substrate height measuring systems (550 through 554) are shown in this example, but any number may be used. The projection lenses may contain both reflective and refractive elements, and are typically telecentric. The projection lens systems (any one of 530 through 534) may be the same as the projection optics 130 in FIG. 1. Substrate 140 either contains a photosensitive layer, such as a photoresist coating, or is itself a photosensitive material, such as a sheet of photosensitive polyimide. The substrate is attached to stage 150, which moves continuously during exposure in straight-line segments in the x-y plane of stationary coordinate system 160. As in other embodiments, the imaging optics may be carried on the stage.

FIG. 6 is a schematic of a continuous direct-write optical lithography system with a single telecentric objective lens system and a SLM with multiple area arrays. The light source 610 is the same as the light source described in FIG. 5, and is configured so as to provide illumination to match the requirements of the individual SLM area arrays 520 through 524. Each individual SLM area array is one or more rectangular arrays of small mirrors that can switch between two or more angular states under computer control. A digital micro-mirror device (DMD) currently available from Texas Instruments is an example of a suitable mirror-array that can switch between two angular states. Mirrors in the "on" state in the SLM area arrays are imaged on the substrate 140 by telecentric projection lens system 630. Light reflected from mirrors in the SLM area arrays in the "off" state travels to SLM beam dump 480 where it is absorbed. Five SLM area arrays are shown in this example but any number may be

used. A double telecentric projection lens system 630 is shown. However, a single telecentric or non-telecentric projection system can also be used. A telecentric design is preferred because the magnification does not change with substrate height, which simplifies calibration of the lithography tool for each substrate. The telecentric projection lens system is a type of projection lens system 130, as in FIG. 1. The stage can move in a plane x-y and also in the z direction of the stationary coordinate system 160. The stage 150 can also have rotation and tilt capability; this may be required for proper substrate alignment (for example, when substrate flatness is an issue). Movement in the z direction will either focus or defocus the projected image on the substrate. A substrate height measuring system 450 can be used to determine the z position of the surface of the substrate 140. The height measuring system can be optical, capacitance or air based. The preferred type is air. Focusing can also be accomplished by moving either the SLM area arrays 520 through 524 or telecentric projection lens system 630 in the z direction. Substrate 140 either contains a photosensitive layer, such as a photoresist coating, or is itself a photosensitive material, such as a sheet of photosensitive polyimide.

Further to the lithography systems of FIGS. 5 & 6, other embodiments of the invention are envisaged which combine a SLM having multiple area arrays with a submultiple number of projection lens systems. For example, a lithography system may have 6 SLM area arrays and 2 projection lens systems, such that each projection lens system images 3 different SLM area arrays at once. Furthermore, the number of projection lens systems need not be limited to a mathematical submultiple—for example, a lithography system may have 7 SLM area arrays and 2 projection lens systems, such that a first projection lens system images 3 SLM area arrays and a second projection lens system images the remaining 4 SLM area arrays. The configuration of these embodiments will be apparent to those skilled in the art. Clearly, there are very many further combinations of SLM area arrays and projection lens systems which follow this teaching and will be apparent to those skilled in the art.

With reference to FIG. 7, a partial cross-section of a SLM 720 is shown. Mirrors 721 are shown in the 'on' position and mirrors 722 are shown in the 'off' position. Light rays 770 are reflected off the surface of the mirrors 721, which are in the 'on' position, toward a substrate (rays 771) and are reflected off the surface of mirrors 722, which are in the 'off' position, toward a beam stop (rays 772). For example, referring to both FIGS. 4 and 7, rays 771 travel through projection lens system 430 and then to the substrate 140, whereas the rays 772 fall outside the acceptance aperture of projection lens system 430 and are collected by beamstop 480. This is the preferred mode of operation, although, other modes of operation may be considered. For example, the rays 772 could fall partly within the acceptance aperture of projection lens system 430, consequently an attenuated signal from the "off" state mirrors would reach the substrate, which may be tolerable.

With reference to FIG. 8, an example is shown of a serpentine path 850 that can be followed by the projected image of a SLM in order to expose the entire surface of the substrate 140. The motion of the image is due to an image movement mechanism. The substrate or the SLM can be mounted on the image movement mechanism. An example of a suitable mechanism is a stage, such as shown in FIGS. 1, 2 and 3. In the case of a flexible substrate a suitable mechanism is a pair of rotatable, spaced apart, axially parallel film drums, such as shown in FIG. 3. In the explanation that follows a configuration of the lithography

system in which the substrate is mounted on a stage is assumed. The following are shown: substrate **140**, serpentine path **850**, distance between straight line segments on the path **851**, substrate coordinate system **853** and stationary coordinate system **860**. The SLM is oriented in such a way that the columns of pixels in the projected image on the substrate are parallel to the straight-line segment portions of the serpentine path, which, for ease of illustration, are parallel to the x-axis of stationary coordinate system **860**. A stage positions the substrate **140** such that the center of the projected image of the SLM is at the beginning of path **850**. In this example, at the beginning of path **850** none of the projected image of the SLM falls on the substrate **140**. As the stage moves in the +x direction, referenced to stationary coordinate system **860**, the center of the projected image of the SLM moves in the -x_s direction, referenced to substrate coordinate system **853**, and traces the first straight section of the serpentine path. The exposure starts when the projected image of the SLM falls on the substrate. The exposure stops after the projected image clears the edge of the substrate. The stage then repositions the substrate in readiness to scan in the -x direction along the second straight section of the path, which is separated from the first straight section by a distance **851** in the y direction, all referenced to stationary coordinate system **860**. This is repeated until the entire substrate is exposed. Clearly, the projected width of the SLM must be greater than or equal to the distance **851** in order to expose the complete substrate. If only certain regions of the substrate need to be exposed, then it may be more efficient to execute a serpentine pattern for each individual region. Although a serpentine path is preferred, other paths could be used as long as they contained straight-line segments for the exposure. It will be clear to those skilled in the art that a serpentine path can also be achieved with a lithography system configuration in which the SLM is mounted on a stage and the substrate is static.

With reference to FIG. 9, an example is shown of a set of serpentine paths **950** through **954** that can be followed by the projected images of a corresponding set of SLM area arrays in order to expose the entire surface of the substrate **140**. The motion of the image is due to an image movement mechanism. The substrate or the SLM can be mounted on the image movement mechanism. An example of a suitable mechanism is a stage, such as shown in FIGS. 1, 2 and 3. In the case of a flexible substrate a suitable mechanism is a pair of rotatable, spaced apart, axially parallel film drums, such as shown in FIG. 3. In the explanation that follows a configuration of the lithography system in which the substrate is mounted on a stage is assumed. Each SLM area array is oriented in such a way that the columns of pixels in the projected image on the substrate **140** are parallel to the straight-line segment portions of the serpentine path, which for ease of illustration, are parallel to the x-axis of stationary coordinate system **860**. A stage positions the substrate **140** such that the centers of the projected images of the SLM area arrays are at the beginning of paths **950** through **954**. In this example, at the beginning of paths **950** through **954** none of the projected images of the SLM arrays fall on the substrate **140**. As the stage moves in the +x direction, referenced to stationary coordinate system **860**, the center of the projected images of the SLM area arrays move in the -x_s direction, referenced to substrate coordinate system **853**, and trace the first straight sections of the serpentine paths. The exposure along any path starts when the projected image of the SLM area array falls on the substrate. The exposure stops along any path after the projected image clears the edge of the substrate. After all exposures have stopped, the stage then

repositions the substrate in readiness to scan in the -x direction along the second straight section of the path, which is separated from the first straight section by a distance **851** in the y direction, all referenced to stationary coordinate system **860**. If this does not cover the entire substrate, then the stage moves in the y direction, referenced to stationary coordinate system **860**, by the distance between paths **950** and **954**, and the above procedure is repeated. Clearly, the projected width of the SLM arrays must be greater than or equal to the distance **851** in order to expose the complete substrate. Note that in this example the separation between consecutive paths **950**, **951**, . . . **954** is twice the spacing **851**; should the separation exceed twice the spacing **851**, then a serpentine motion with more straight sections can be employed. This explanation is relevant to the multiple SLM area array lithography systems of FIGS. 5 & 6, for which paths **950** through **954** correspond to SLM area arrays **520** through **524**.

Referring to FIGS. 1 and 8, patterns of elements in the "on" state that correspond to features printed on substrate **140** must shift across the SLM **120** in such a way that they appear stationary, on average, to the constantly moving substrate. If the stage **150** is moving at constant speed v along one of the straight-line segments of serpentine path **850** (the stage is moving in a patterning direction), then this is accomplished by shifting the SLM pattern by one row at regular time intervals, where the time interval T is given by:

$$T = \frac{pM}{v} \quad (1)$$

where p is the row pitch of the elements (the Texas Instruments DMD mirrors have the same pitch for rows and columns) and M is the magnification of the projection lens system **130**. As an example, the Texas Instruments DMD is available with a mirror pitch of 13.7 microns and the minimum mirror cycle time is 102 microseconds. If the projection lens system **130** has a magnification of 2.0, then the stage speed is approximately 269 mm/s. If the dose delivered is inadequate to expose the substrate or the stage speed required is beyond the capability of the stage system, then the actual mirror cycle time used may need to be longer. However, the mirror cycle time and stage speed must always satisfy equation (1).

FIG. 10 illustrates the shifting of patterns on the SLM and the corresponding image on the substrate. In this example, the substrate is on a stage and moves at constant speed in the x direction during exposures. The following are shown, with reference also to FIG. 1: part of SLM **120**, which is an array of elements **1000** with an area of 4 rows by 6 columns; a corresponding part of substrate **140**, which is an array of pixels **1002** with an area of 4 rows by 6 columns; resultant image **1007** with projected row pitch (width of a pixel) **1008**. The resultant image shows one possible latent image on the substrate due to completion of the entire series of exposures. The edge placement and corner rounding in a latent image will be discussed in detail below. "Snapshots" of the corresponding parts of the SLM and substrate are shown at equally spaced times T1 through T7, where the time interval satisfies equation (1); the parts of the SLM and substrate are indicated in the figure by M and S, respectively. The SLM array **1000**, the substrate array **1002** and the resultant image **1007** are drawn as if viewed from a position directly above them and looking down in the -z direction of stationary coordinate system **160**. For ease of illustration, in each

11

“snapshot” the SLM and substrate arrays are shown next to each other. The projected row pitch **1008** in the resultant image **1007** is the row pitch in the SLM array **1000** times the magnification of the projection lens system **130**. However, for ease of illustration, in each “snapshot” the SLM and substrate arrays are shown having the same size and orientation. The grid shown on the arrays **1000** and **1002**, and the image **1007** is for reference only. A light square in **1000** corresponds to an SLM element in the “on” state, while a dark square corresponds to one in the “off” state. The light and dark areas in **1002** correspond to the states of the SLM elements for that “snapshot”. For example, at time T_1 the substrate is receiving light at pixels located at **R1C4** and **R1C5** from mirrors in the SLM array at positions **R4C4** and **R4C5** (where the nomenclature **R1C4** represents the pixel/element at row **R1** and column **C4**). At time T_1 the bottom edge of the substrate array **1002** is aligned with substrate position coordinate **1**. At time T_2 the substrate has moved by one row and the bottom edge of the substrate is now aligned with substrate position coordinate **2**. The time elapsed between T_2 and T_1 satisfies equation (1). The particular feature pattern used as an example in FIG. **10** is shown in its entirety at time T_4 on both the SLM and the substrate arrays. It can be seen that the edge of this feature pattern first appears at T_1 , scrolls across the SLM array **1000** between times T_2 and T_6 and has moved off the SLM array **1000** by T_7 . On the substrate array **1002**, the feature pattern does not appear to move. This can be most clearly seen at times T_3 and T_4 . However, because the substrate is moving at constant speed while the SLM is stationary, the projected pattern does in fact move on the substrate by the projected row pitch **1008** between any two consecutive snapshot times. Note that for ease of illustration the patterns shown on the substrate arrays **1002** do not show any blurring or optical interference effects.

FIG. **11** shows the substrate array **1002** with a line segment **AB** positioned in the center of column **C4**. Light intensity and resultant dose profiles will be determined on the surface of the substrate array in the position indicated by line segment **AB**. Note that the position of **AB** is such that it crosses the “trailing edge” of the exposure pattern shown in FIG. **10**.

The consequences of the movement of the projected pattern across the substrate surface during exposure will now be examined. FIG. **12** shows instantaneous light intensity distributions on substrate array **1002** from FIG. **10**; the distributions are along the position of line segment **AB** as shown in FIG. **11**. Note that in FIG. **12** the line segment **AB** is shown to extend from -2 to 1.5 on the abscissa. In FIG. **12**, six distributions are shown at intervals of $T/10$ starting at T_3 and then every $T/10$, where T is defined in equation (1) above. The substrate is moving with constant velocity. The abscissa represents substrate displacement x_s (as shown in FIGS. **8** and **9**) measured in units of projected row pitch (as defined above in reference to FIG. **10**). The following are shown in FIG. **12**: light intensity profiles **1200**, **1201**, **1202**, **1203**, **1204** and **1205**; 50% light intensity marker **1209**; 50% position marker **1210**; and projected row pitch **1215**. The shape of light intensity profiles **1200**, **1201**, **1202**, **1203**, **1204** and **1205** is shown as being Gaussian; however, the actual shape depends on details of the optics. The instantaneous light intensity as a function of position on the substrate array **1002** at time T_3 is represented by light intensity profile **1200**. Light intensity profile **1200** is positioned such that the intersection of the 50% marker **1209** on the abscissa corresponds to the boundary between rows **R3** and **R4** on the substrate array. The region between -1 and 0 on the abscissa

12

corresponds to **R4** on the substrate array, the region between 0 and 1 corresponds to **R3** and the region between 1 and 2 corresponds to **R2**. As the stage moves substrate array **1002** in the $+x$ direction, the instantaneous light intensity profile advances across the substrate array in the $-x_s$ direction. The light intensity profiles **1201**, **1202**, **1203**, **1204** and **1205** are for times T_3 plus $T/10$, $2T/10$, $3T/10$, $4T/10$ and $5T/10$, respectively. The light intensity profile advances across the substrate in the $-x_s$ direction by one-half of the projected row pitch during $T/2$. In this example, at T_3 plus $T/2$ the elements in SLM array **1000** switch from the pattern shown at T_3 to the pattern shown at T_4 . Looking specifically at the array elements responsible for generating the light intensity profiles: the element at **C4R4** switches from “on” to “off”, the elements at **C4R3** and **C4R2** remain “on” and the element at **C4R1** switches from “off” to “on”. The effect is to shift the light intensity profile from the position of **1205** to a new position which is one times the projected row pitch in the $+x_s$ direction.

FIG. **13** follows on from FIG. **12** showing the light intensity profiles for the next period $T/2$. After the elements switch at time $T_3+T/2$ the light intensity profile moves from the position of **1205** (see FIG. **12**) to that of **1300** (see FIG. **13**). As the stage continues to move the substrate array **1002** in the $+x$ direction, the instantaneous light intensity profile advances across the substrate array in the $-x_s$ direction. The light intensity profiles **1301**, **1302**, **1303**, **1304** and **1305** are for times T_3 plus $6T/10$, $7T/10$, $8T/10$, $9T/10$ and $10T/10$, respectively. Light intensity profile **1305** is at time T_3+T , which is the same as time T_4 . The light intensity profile advances across the substrate in the $-x_s$ direction by one-half of the projected row pitch during $T/2$. Consequently, the position of light intensity profile **1305** at T_4 is the same as for profile **1200** at T_3 .

FIGS. **12** and **13** have shown how the light intensity distribution varies over the time interval between T_3 and T_4 . FIG. **14** shows the resultant dose distribution for the same position on substrate array **1002**—along line segment **AB**. The light intensity distributions **1200** and **1300** in FIGS. **12** and **13** are Gaussian with $\sigma=0.43$. One can see from FIG. **14** that the resultant dose profile **1401** has a similar form to the original Gaussian.

The following are shown in FIG. **14**: resultant dose profile **1401**, 50% resultant dose marker **1404**, 50% position marker **1405** and projected row pitch **1215**. Because the elements in SLM array **1000** in FIG. **10** are switched when the substrate array **1002** has moved by one-half of the projected row pitch **1008**, the 50% resultant dose marker **1404** intersects the resultant dose profile **1401** at position **1405**, which is the same as position **1210** in FIGS. **12** and **13**. This is due to the symmetrical nature of the process shown in FIGS. **12** and **13**. Other choices of element switching time, besides $T_n+T/2$ (where $n=1, 2, 3 \dots$), could be used (such as $T_n+T/5$). The shape of the resultant dose profile would be the same as **1401**, but the 50% resultant dose location on the abscissa would be shifted from 0 . Clearly, modulating the switching time can be used to control the position of printed pattern edges. However, it is preferred to keep the switching time constant. The shape of the dose distribution will not usually be the same as the instantaneous light intensity profiles. This means that the dose profile for edges parallel to the direction of stage motion will differ from those that are orthogonal. Edges parallel to the direction of stage motion are not constantly moving, consequently the dose profile on the substrate for such an edge will be identical to its instantaneous light intensity profile.

13

Referring back to FIG. 10, the process of switching the elements in SLM array 1000 at times $T_n + T/2$ (where $n=1, 2, 3, \dots$) is repeated until the pattern has completely scrolled off the SLM array 1000, which in this example is at time $T7$. Since the time interval between any two consecutive “snapshot” times is equal to T from equation (1), the switching times are equal to $(T1+T2)/2, (T2+T3)/2, (T3+T4)/2, (T4+T5)/2, (T5+T6)/2$ and $(T6+T7)/2$ respectively. Because the dose is additive, the final dose profile along line segment AB will have the same shape as resultant dose profile 1401 in FIG. 14. FIG. 15 shows the total dose profile 1501. The following are shown in FIG. 15: total dose profile 1501, 50% total dose marker 1504, 50% position marker 1505, exposed region 1506, unexposed region 1507 and projected row pitch 1215. It is preferred to adjust the total dose so that, after development, the edge of the printed feature is at the 50% position marker 1505. In which case, the region with more than 50% total dose is the exposed region 1506, while the region with less than 50% total dose is the unexposed region 1507. Under these conditions, the final developed pattern would be similar to the resultant image 1007 in FIG. 10—light areas correspond to exposed regions 1506 and dark areas correspond to unexposed regions 1507. Except for some corner rounding, all the pattern edges line up with the reference grid. Slight changes in exposure dose will affect vertical and horizontal dimensions differently. This is a practical problem only if the slope of the light intensity profile at and around 50% light intensity is not steep enough (a steep slope allows sufficient line width control, assuming reasonable exposure and processing variations).

Consider a lithography tool as in FIGS. 1 and 10 described above. The dose distribution along the x direction on the surface of the substrate is given by the following equation:

$$D(x) = N \int_0^T I_w(x, t) dt \quad (2)$$

where N is a constant, $I_w(x,t)$ is the time dependent light intensity distribution at the surface of the substrate, and time T satisfies equation (1). If the substrate is moving at constant speed v , then the light intensity for the moving substrate, I_w , is related to the light intensity for the substrate at rest, I , by:

$$I_w(x,t) = I(x+vt, t) \quad (3)$$

Between $t=0$ and $t=T/2$ the elements in the SLM are in one state and shift at $t=T/2$ by one row, i.e.;

$$\begin{aligned} I(x, t) &= I_0(x) & 0 < t < T/2 \\ I(x, t) &= I_0(x - pM) & T/2 < t < T \end{aligned} \quad (4)$$

Where $I_0(x)$ is the intensity distribution for a single SLM element with the substrate at rest, p is the row pitch of the SLM array elements and M is the projection lens system magnification. Using equations (1), (3) and (4), equation (2) can be written as:

$$D(x) = N \left[\int_0^{T/2} I_0(x + vt) dt + \int_{T/2}^T I_0(x + vt - vT) dt \right] \quad (5)$$

14

As an example, assume the distribution $I_0(x)$ is Gaussian in form. Then for 10 rows of elements in the “on” state the intensity distribution at the substrate would be:

$$I_0(x) = \frac{1}{2.51\sigma} \int_0^{10} e^{-(x-y)^2/2\sigma^2} dy \quad (6)$$

where σ^2 is the variance.

Equations (5) and (6) are examples of the form of equations used to calculate the dose distributions and intensity distributions shown in the Figures.

In order to make fine adjustments to the location of feature edges, a “gray level” technique can be used. When such a technique is implemented on apparatus such as that shown in FIGS. 1 through 6, it is required that the image of an individual element of the SLM produced by the projection lens system must be “blurred” i.e. the element is not clearly resolved. This “blurring” can be accomplished in various ways including defocusing, using a microlens array or a diffuser or, more commonly, by adjusting the numerical aperture of one of the lenses in the projection lens system to decrease the resolution to the desired value. The preferred method is defocusing. The technique can be understood by referring to FIG. 16.

FIGS. 16 through 19 illustrate examples of “gray level” edge shifting on a pattern edge that is orthogonal to the direction of substrate motion during exposure; in these examples the substrate is assumed to be moving in the same direction at constant speed during exposure. FIGS. 16 through 19 are very similar to FIG. 10. The significant difference is the displacement of the “trailing edge” of the resultant image by a fraction of a pixel; for example, examination of the “trailing edge” of the resultant image 1600 in FIG. 16 shows a displacement 1601 which is 0.5 times the row pitch 1008. Note that for ease of illustration the patterns shown on the substrate arrays 1002 do not show any blurring or optical interference effects.

In FIG. 16 the sequence of patterns on SLM arrays 1000 are identical to the patterns shown in FIG. 10 at times $T1, T2, T3, T4$ and $T6$. However, at time $T5$ the elements in SLM array 1000 at locations R3C2, R3C3, R3C4 and R3C5 are in the “on” state in FIG. 16 and in the “off” state in FIG. 10. Also, at time $T7$ elements in SLM array 1000 at locations R1C2, R1C3, R1C4 and R1C5 are in the “on” state in FIG. 16 and in the “off” state in FIG. 10. With reference to substrate section 1002 in FIG. 16, pixels R4C2, R4C3, R4C4 and R4C5 are exposed at times $T5$ and $T7$, but not at times $T1, T2, T3, T4$ or $T6$. All other rows of the pattern are exposed for four time periods—for example, pixels R1C4 and R1C5 were exposed at times $T1, T2, T3$ and $T4$, while pixels R2C2, R2C3, R2C4 and R2C5 were exposed at times $T2, T3, T4$ and $T5$. The effect of the two time period only exposure in row R4 is to produce an edge displacement 1601 of roughly 0.5 times the width of the projected row pitch 1008, as can be seen in the resultant image 1600.

The sequence of exposures in FIG. 17 produces an edge displacement 1701 of roughly 0.5 times the width of the projected row pitch 1008, as can be seen in the resultant image 1700. This resultant image 1700 is identical to the resultant image 1600 in FIG. 16; however, the two resultant images are produced with different sets of exposure patterns. The exposure patterns in the 2 figures are different at times $T4, T5, T6$ and $T7$. These 2 examples are certainly not exhaustive. One can easily imagine other sequences of exposure patterns that give the same resultant image.

FIG. 18 illustrates a further example of “gray level” edge shifting, in this example the trailing edge displacement **1801** is 0.25 times the row pitch **1008**. The sequence of patterns on SLM array **1000** shown in FIGS. 10 and 18 at times T1, T2, T3, T4, T6 and T7 are identical. However, at time T5 elements in SLM array **1000** at locations R3C2, R3C3, R3C4 and R3C5 are in the “on” state in FIG. 18 and in the “off” state in FIG. 10. With reference to substrate section **1002** in FIG. 18, pixels R4C2, R4C3, R4C4 and R4C5 are exposed at time T5, but not at times T1, T2, T3, T4, T6 or T7. All other rows of the pattern are exposed for four time periods. The effect of the one time period exposure in row R4 at time T5 is to produce an edge displacement **1801** of roughly 0.25 times the width of the projected row pitch **1008**, as can be seen in resultant image **1800**.

FIG. 19 illustrates a further example of “gray level” edge shifting, in this example the trailing edge displacement **1901** is 0.75 times the row pitch **1008**. The sequence of patterns on SLM array **1000** shown in FIGS. 19 and 10 at times T1, T2, T3 and T4 are identical. However, at time T5 elements in SLM array **1000** at locations R3C2, R3C3, R3C4 and R3C5 are in the “on” state in FIG. 19 and in the “off” state in FIG. 10. At time T6 elements in SLM array **1000** at locations R2C2, R2C3, R2C4 and R2C5 are in the “on” state in FIG. 19 and are in the “off” state in FIG. 10. Also, at time T7 elements in SLM array **1000** at locations R1C2, R1C3, R1C4 and R1C5, are in the “on” state in FIG. 19 and are in the “off” state in FIG. 10. With reference to substrate section **1002** in FIG. 19, pixels R4C2, R4C3, R4C4 and R4C5 are exposed at times T5, T6 and T7, but not at T1, T2, T3 or T4. All other rows of the pattern are exposed for four time periods. The effect of the three time period exposure in row R4 at times T5, T6 and T7 is to produce an edge displacement **1901** of roughly 0.75 times the width of the projected row pitch **1008**, as can be seen in resultant image **1900**.

FIG. 20 illustrates an example of “gray level” edge shifting on a pattern edge that is parallel to the direction of substrate motion during exposure; in this example the substrate is assumed to be moving in the same direction at constant speed during exposure. FIG. 20 is very similar to FIG. 10. The significant difference is the displacement of an edge of the resultant image by a fraction of a pixel; for example, examination of the edge of the resultant image **2000** in FIG. 20 shows a displacement **2001** which is 0.25 times the column pitch **2003**.

In FIG. 20 the sequence of patterns on SLM array **1000** shown in FIGS. 20 and 10 at times T1, T2, T4, T5, T6 and T7 are identical. However, at time T3 elements in SLM array **1000** at locations R2C6, R3C6 and R4C6 are in the “on” state in FIG. 20 and in the “off” state in FIG. 10. With reference to substrate section **1002** in FIG. 20, pixels R1C6, R2C6 and R3C6 are exposed at time T3 but not at times T1, T2, T4, T5, T6 or T7. All other pixels on the substrate array **1002** are exposed for four time periods. The effect of the one time period exposure in column C6 at time T3 is to produce an edge displacement **2001** of roughly 0.25 times the width of the projected column pitch **2003**, as can be seen in resultant image **2000**.

Further to edge displacements, using one or more pixel exposures near a corner will affect the degree of corner rounding. For example, with reference to resultant image **1007** in FIG. 10, exposures at R1C1 or at both R1C2 and R2C1 will change the corner rounding at location R2C2.

The edge displacements shown in the resultant images of FIGS. 16 through 20 are only approximate; the actual displacements will depend on the detailed shape of the instantaneous light intensity distribution at the edges of the

exposure patterns. A more accurate determination can be made by using a slightly modified form of equation (5) for the dose distribution, including the light intensity distribution appropriate to the mirror section states for each half of the 7 time periods. This modified form of equation (5) was used to calculate resultant dose distributions along the position of line segment AB on substrate array **1002** (see FIG. 11) for the exposure pattern examples given in FIGS. 10, 16, 17, 18 and 19. In these calculations it is assumed that the instantaneous light intensity distribution shape is Gaussian with a σ value of 0.43. These resultant dose distributions are shown in FIG. 21.

In FIG. 21 resultant dose profiles **2101**, **2102**, **2103** and **2104** correspond to FIGS. 10, 16, 18 and 19, respectively; resultant dose profile **2102** also corresponds to FIG. 17. 50% position markers **2105**, **2106**, **2107**, **2108** are for dose profiles **2101**, **2102**, **2103** and **2104**, respectively. With reference also to the resultant images in FIGS. 10, 16, 17, 18 and 19, the regions between -1 and 0 and 0 and 1 on the abscissa in FIG. 21 correspond to R4 and R3, respectively, in the resultant images. 50% position marker **2105** of resultant dose profile **2101** was calculated for the example given in FIG. 10 and intersects the abscissa at 0 . This result is consistent with the resultant image **1007** shown in FIG. 10. 50% position marker **2106** of resultant dose profile **2102** was calculated for the example given in FIG. 16 and intersects the abscissa at -0.5 . This result is in agreement with the value of edge displacement **1601**. 50% position marker **2107** of resultant dose profile **2103** was calculated for the example given in FIG. 18 and intersects the abscissa at -0.20 . This result is slightly different from the edge displacement **1801** value of 0.25 . 50% position marker **2108** of resultant dose profile **2104** was calculated for the example given in FIG. 19 and intersects the abscissa at -0.80 . This result is slightly different from the edge displacement **1901** value of 0.75 .

It should be noted that the examples given above are simplistic and ignore interference effects from adjacent elements of the SLM, the rigorously correct shape of the light intensity distribution, and the finite contrast of the photosensitive substrate. In general, the correct dose for a particular edge displacement will need to be determined experimentally. However, once the relationship between dose and edge displacement is determined, the technique can be used to compensate for misalignment and distortion of the substrate, distortion and aberrations in the projection lens system, and non-uniform illumination. This technique could be used to relax the specification of the optics, thus reducing the cost of the optics.

The preferred SLM device is the two-state DMD from Texas Instruments which has a rectangular array of mirrors—1024 mirrors wide by 768 mirrors deep. The scan direction during exposure of the substrate is preferably orthogonal to the 1024 width in order to minimize the number of times the stage must reverse direction along its serpentine path (see FIG. 8). Since the array is 768 rows deep, the exposure patterns will scroll across the array in 768 discrete steps and there will be 768 opportunities to adjust edge locations using the “gray level” technique outlined above. This allows for an edge placement resolution of $1/768^{th}$ the size of the projected row pitch of the DMD in the resultant image. In practice, one rarely needs more than $1/32^{nd}$. Consequently, 32 equally spaced edge positions can be chosen and the extra resolution can be used to compensate for non-uniform illumination of the substrate.

The minimum feature size that can be printed on the substrate depends on the characteristics of the light intensity profile. This will be explained with reference to FIGS. 22 through 27.

FIG. 22 illustrates another example of the shifting of patterns on the SLM and the corresponding image on the substrate. As in previous examples, the substrate is on a stage and moves at constant speed in the x direction during exposures. The following are shown, with reference also to FIG. 1: part of SLM 120, which is an array of elements 2200 with an area of 5 rows by 6 columns; a corresponding part of substrate 140, which is an array of pixels 2202 with an area of 5 rows by 6 columns; resultant image 2207 with projected row pitch (width of a pixel) 1008. "Snapshots" of the corresponding parts of the SLM and substrate are shown at equally spaced times T1 through T8, where the time interval satisfies equation (1). This figure is similar to FIG. 10.

FIG. 23 shows the substrate array 2202 with line segments CD, EF, GH and IJ positioned in the center of columns C2, C3, C4 and C5. Light intensity and resultant dose profiles will be determined on the surface of the substrate array in the positions indicated by the line segments. Note that the positions of the line segments are such that they cross both the "trailing edge" and "leading edge" of the exposure pattern shown in FIG. 22.

FIG. 24 shows resultant dose distributions for the exposed substrate 2202, as detailed in FIG. 22. A Gaussian shape with a σ value of 0.43 is assumed for the instantaneous light intensity distributions used to derive the resultant dose distributions. The following are shown in FIG. 24: resultant dose profiles 2400, 2401, 2402 and 2403 along line segments CD, EF, GH and IJ, respectively; 50% position markers 2405, 2406 and 2407 corresponding to dose profiles 2401, 2402 and 2403, respectively; 50% position markers 2404 and 2408, both corresponding to dose profile 2400; and projected row pitch 1215. Note that the line segment CD is shown to extend from -2 to 6 on the abscissa; line segments EF, GH and IJ extend over the same values on the abscissa, but are not shown so as to avoid cluttering the figure. The regions between -1 and 0, 0 and 1, 1 and 2, 2 and 3, and 3 and 4 on the abscissa in FIG. 24 correspond to R5, R4, R3, R2, and R1, respectively, on the resultant image 2207 in FIG. 22. If the total dose is adjusted such that the edge of printed features is at the 50% position markers, which is preferred, than the final developed pattern would be similar to the resultant image 2207 in FIG. 22. It should be noted that resultant dose profile 2400 in FIG. 24 never rises higher than about 70% of dose profiles 2402 and 2403, and that the distance between the 50% position markers 2404 and 2408 is slightly less than the projected row pitch 1008. Clearly, under these conditions the minimum feature size is roughly the same as the projected row pitch 1008. The "gray level" technique described earlier can be used to adjust the width of such a feature—for example, decreasing the total dose for pixel R4C2 in substrate array 2202 of FIG. 22 will reduce the height of resultant dose profile 2400, which decreases the size of the printed feature. However, the feature dimension changes rapidly with small changes in dose near the top of dose profile 2400. Furthermore, there is always some noise and uncertainty in the total dose which places a practical limit on this approach.

FIG. 25 illustrates a further example of the shifting of patterns on the SLM and the corresponding image on the substrate. As in previous examples, the substrate is on a stage and moves at constant speed in the x direction during exposures. In FIG. 25 examples of "gray level" edge shifting

on various sizes of feature are shown, where the shifted edges are orthogonal to the direction of substrate motion during exposure. The following are shown, with reference also to FIG. 1: part of SLM 120, which is an array of elements 1000 with an area of 4 rows by 6 columns; a corresponding part of substrate 140, which is an array of pixels 1002 with an area of 4 rows by 6 columns; resultant image 2507 with projected row pitch (width of a pixel) 1008. "Snapshots" of the corresponding parts of the SLM and substrate are shown at equally spaced times T1 through T7, where the time interval satisfies equation (1). This figure is similar to FIG. 10.

FIG. 26 shows the substrate array 1002 with line segments KL, MN, OP, QR and ST positioned in the center of columns C2, C3, C4, C5 and C6. Light intensity and resultant dose profiles will be determined on the surface of the substrate array in the positions indicated by the line segments. Note that the positions of the line segments are such that they cross the "trailing edge" and "leading edge" of the exposure pattern shown in FIG. 25.

FIG. 27 shows resultant dose distributions for the exposed substrate 1002, as detailed in FIG. 25. A Gaussian shape with a σ value of 0.43 is assumed for the instantaneous light intensity distributions used to derive the resultant dose distributions. The following are shown in FIG. 27: resultant dose profiles 2700, 2701, 2702, 2703 and 2704 along line segments KL, MN, OP, OR and ST, respectively; 50% position markers 2710 and 2716 both corresponding to dose profile 2704; 50% position markers 2710 and 2713 both corresponding to dose profile 2703; 50% position markers 2711 and 2714 both corresponding to dose profile 2702; 50% position markers 2712 and 2715 both corresponding to dose profile 2701; and projected row pitch 1215. Note that the line segment KL is shown to extend from -2 to 5 on the abscissa; line segments MN, OP, OR and ST extend over the same values on the abscissa, but are not shown so as to avoid cluttering the figure. The regions between -1 and 0, 0 and 1, 1 and 2, and 2 and 3 on the abscissa in FIG. 27 correspond to R4, R3, R2, and R1, respectively, on the resultant image 2507 in FIG. 25. If the total dose is adjusted such that the edge of printed features is at the 50% position markers, which is preferred, than the final developed pattern would be similar to the resultant image 2507 in FIG. 25. It should be noted that resultant dose profile 2700 in FIG. 27 never rises higher than about 45% of dose profile 2704, and therefore does not print. Resultant dose profile 2700 is due to exposure by alternating single adjacent pixels, as can be seen by investigating column C2 of substrate section 1002 at times T2, T3, T4 and T5 in FIG. 25. This is in contrast to the example of FIG. 22 where a single pixel exposure created a dose profile that did print. With reference to FIGS. 25 and 27, the features printed in columns C3, C4 and C5 are all roughly 1.5 times the projected row pitch 1008 in width as can be seen, for example, by examining the distance between 50% position markers 2711 and 2714 of resultant dose profile 2702. It appears that when a feature is at some arbitrary location with respect to the projected SLM element grid then the minimum (practical) feature size is roughly 1.5 times the projected row pitch; this is in contrast to the minimum feature size of roughly 1.0 times the projected row pitch seen for features located on the projected SLM element grid—see FIGS. 22 and 24.

With reference to FIG. 28, a block diagram for an optical lithography system of the invention is shown. Design data, which resides on the design data storage device 2804, describes what the system should print and is input to the data preparation computer 2805 for translating into a form

suitable for the decompression electronics **2807**. The data preparation computer **2805** can also modify the data to compensate for previously measured substrate distortion. Substrate alignment system **2803** can be used to measure the substrate distortion. The design data is typically in a CAD (Computer Aided Design) format or a mask standard format such as GDSII. The design data storage device may be one or more tapes or disk drives. The data preparation computer can be any general-purpose computer such as an IBM PC. After computation by the data preparation computer, the data is stored on one or more fast disk drives **2806**. The preferred form of this data can be understood by reference to the resultant image in FIG. **19**. The entire area of the substrate **140** is divided into small squares with a pitch equal to the magnified pitch of the SLM array **120**, substrate array **1002** provides a small-scale example. Each pixel in the array covering the substrate is assigned a dose value that is based on the feature pattern and a look-up table value. The look-up table values are determined experimentally and take into account the distortions and aberrations of projection lens system **130** and the illumination non-uniformity from the illumination source **110**. As an example, dose values are derived based on the feature pattern of resultant image **1900**, assuming 32 gray levels, where 31 corresponds to 100% exposure. The following pixels will have a dose value of 31:

R1C4, R1C5, R2C2, R2C3, R2C4, R2C5, R3C2,
R3C3, R3C4, R3C5

The following will have a dose value of 0:

R1C1, R1C2, R1C3, R1C6, R2C1, R2C6, R3C1,
R3C6, R4C1, R4C6

The following pixels will have a dose value intermediate between 0 and 31, based on the intended edge location **1901**:

R4C2, R4C3, R4C4, R4C5

For convenience, we will assign a value of 24 to the above. Next, a look-up table is used to modify the dose values to account for distortions, aberrations and illumination nonuniformity of the system. Since the preferred SLM, the Texas Instruments DMD device, can switch mirror states every 102 microseconds and has 1024 rows and 768 columns, this means that the fast disk drives **2806** need to deliver 1 row of 1024 pixels every 102 microseconds. With 32 gray levels this is a data rate of roughly 6.3 megabytes/second. This data rate is easily within present day capabilities of disk drive arrays.

Again referring to FIG. **28**, alignment of the substrate **140** to the stage **150** and projection lens system **130** is determined by reflecting substrate alignment system light **2892** off features on the substrate **140** into substrate alignment system **2803**. The substrate alignment system is preferably a "machine vision" system that compares arbitrary features on the substrate to previously stored images or idealized images, such as a cross or a circle, in order to find a match. The substrate alignment system light could come from illumination source **110** by way of SLM **120** and projection lens system **130**, or from an external source. After reflecting off features on the substrate the light could travel directly to the substrate alignment system, as shown, or could first travel through the projection lens system ("through the lens" alignment). The light reflected off features on the substrate could also travel through the projection lens system, reflect off the SLM and then pass into the substrate alignment system. Stage metrology system **2802** receives stage position information from stage position optical sensor **2891**,

which can be based on laser interferometers or linear scales, and sends information to control computer **2801**. In turn, the control computer sends signals to the stage x, y motors which then servo to the correct location. If edge blurring is accomplished by defocusing, which is the preferred technique, then the control computer commands the stage to servo in z until a suitable gap value is achieved. The gap value is measured by the substrate height detector **450** by way of substrate height detection medium **490**, which is preferably air. Other types of detection techniques, such as optical or capacitance, would also work. The gap value (defocus) is chosen to produce the desired amount of feature edge blurring in the image projected onto the substrate. Constant servoing to maintain this gap value is needed to compensate for local substrate height variations. Rather than move the stage in the z-direction, it would also be acceptable to move the projection lens system **130** or SLM **120** in the z-direction instead. Next, the control computer commands the fast disk drives **2806** to send the first row of data to the decompression electronics **2807**, which loads the first frame of mirror state data to the SLM memory **2808**.

To understand the function of the decompression electronics **2807** it is necessary to first understand the requirements of the SLM **120**. All of the mirrors in the SLM switch states at the same time. The states of all mirrors are individually determined by values stored in the SLM memory **2808**. Therefore, the requirement for the decompression electronics is that it must load the entire SLM memory with new mirror-state values every mirror clock cycle. For the Texas Instruments DMD device, this is every 102 microseconds. The decompression electronics must translate the dose values for each image pixel into a sequence of mirror states that shift with the moving substrate. A simplified example based on FIG. **19** can illustrate how this could be accomplished. For any pixel in the resultant image **1900**, 5 dose levels are possible due to the four mirror clock cycles used to shift each row across the mirror section **1000**. For example, pixel **R4C2** in substrate section **1002** can be exposed at time **T4**, **T5**, **T6** and **T7**, as can be seen by inspecting FIG. **19**. The actual exposure was only at times **T5**, **T6** and **T7** for this pixel. Any of the five possible exposure sequences can be represented by a string of 0's and 1's that correspond to the mirror state at the 4 exposure times. For example, for **R4C2** the string would be 0111. A suitable set of 5 exposure sequences would be:

0000 0001 0011 0111 1111

There are other possible sequences that give the same dose, such as 1000 rather than 0001. This degree of freedom can be used to compensate for illumination non-uniformity from illumination source **110**. The dose levels that correspond to the exposure sequences are defined to be 0, 1, 2, 3, and 4. Prior to the mirrors switching at time $(T4+T3)/2$, dose levels for all of the pixels in row **4** (**R4**) of SLM array **1000** are sent from the fast disk drives **2806** to the decompression electronics **2807**. The sequences that correspond to each possible dose level are stored in a look-up table in the decompression electronics. Again using pixel **R4C2** as an example, its dose level would be 3 which corresponds to the sequence 0111. Starting in the state shown at **T3**, the SLM memory **2808** would have a 0 state loaded for the mirror in the fourth row and second column, **R4C2**, of the substrate array **1000**. After the mirrors switch to the state shown at **T4**, the decompression electronics loads the SLM memory with the second digit in the exposure sequence (1) in the third row and second column, **R3C2**, of the substrate array **1000**. The

21

mirrors switch state at $(T5+T4)/2$. After the mirrors switch to the state shown at T5, the decompression electronics loads the SLM memory with the third digit in the exposure sequence (1) in the second row and second column, R2C2, of the substrate array 1000. The mirrors switch state at $(T6+T5)/2$. After the mirrors switch to the state shown at T6, the decompression electronics loads the SLM memory with the fourth digit in the exposure sequence (1) in the first row and second column, R1C2, of the substrate array 1000. The mirrors switch state at $(T7+T6)/2$. The principal of operation is the same for the much larger Texas Instruments DMD array. The decompression electronics must contain a memory large enough to hold a dose level code for each of the mirrors in the SLM and a look-up table. The decompression electronics also contains logic components to handle the bookkeeping. Because all of the mirror values need to be determined and loaded into the SLM memory during the 102 microseconds mirror clock cycle, many mirror values need to be computed in parallel. For example, if it takes 100 nanoseconds to calculate the next state for a single mirror, then the computations for roughly 800 mirrors must clearly be done in parallel.

The control computer 2801 commands the stage 150 to move to the start location and accelerate to the correct constant speed. Control computer 2801 also commands illumination source 110 to emit light of the correct intensity to match the requirements of photosensitive substrate 140. This is usually done with a variable optical attenuator. Data from the stage metrology system 2802 tells the control computer when the substrate is in the correct position to begin exposure. Again referring to FIG. 19, at time T1 minus T/2, where T satisfies equation (1), the bottom of substrate array 1002 would be at substrate position $1/2$. At this time, the control computer commands the spatial light modulator to switch all of the mirrors to the states corresponding to the new values stored in the SLM memory 2808. At the same time the control computer 2801 commands the fast disk drives 2806 to send the next row of data to the decompression electronics 2807, which loads the second frame of mirror state data into the SLM memory. This process is repeated until the edge of the substrate is reached, at which time the control computer commands the stage to execute a turn-around; the system is then ready to start exposing the next segment of the serpentine path, as shown in FIG. 8. This is repeated until the entire patterned area of the substrate has been exposed.

The method of operation discussed above with reference to FIG. 28 can readily be extended to operate an optical lithography system of the invention comprising multiple SLM area arrays.

Some embodiments of the optical lithography tool have an SLM with multiple area arrays which are arranged in multiple rows, where all of the following apply: (1) the rows of area arrays are perpendicular to the direction of movement of the projected image of the SLM arrays on the substrate; (2) the area arrays are individually aligned so that the rows of elements in the arrays are also perpendicular to the direction of movement of the projected image of the SLM arrays on the substrate; and (3) the positions of the area arrays are staggered from one row to the next. An example of such an arrangement is shown in FIG. 29. In FIG. 29 the area arrays 2910 are arranged in three rows, where the rows are perpendicular to the direction of movement 2950 of the projected image of the SLM arrays on the substrate (direction 2950 is also the direction in which pattern data is scrolled across the elements of the area arrays). The arrangement of the SLM area arrays shown in FIG. 29 allows a

22

substrate to be exposed without having to follow a serpentine path as shown in FIG. 9 (the path in FIG. 9 is suitable for a single row of SLM area arrays in which there will be gaps between arrays). The staggered arrangement allows the gaps between the arrays in one row to be covered by arrays in other rows. The example shown in FIG. 29 shows coverage without gaps where there is no overlap of coverage in the 3 rows; however, some embodiments may have overlap in coverage. Furthermore the arrangement of SLM area arrays within a roughly circular area (indicated by circle 2960 in FIG. 29) makes efficient use of the imaging optics, which will typically consist of circular components. For example an image of the seven SLM arrays in FIG. 29 can all be simultaneously projected onto a substrate by a projection lens system comprising a single set of circular lenses.

FIG. 30 shows the optical lithography tool of FIG. 4 with the addition of a mirror 485, a light switching mechanism 121 and a second SLM beam dump 481. In this example the light switching mechanism 121 is a second SLM. A light path from a light source (comprising components 410 through 417) to a substrate 140, via a SLM 120 is indicated by light rays 170. The light switching mechanism 121 is positioned in serial with the SLM 120 on the light path. In this example, a mirror 485 has also been inserted on the light path to accommodate the SLM 121 in the position shown. Clearly, many other optical configurations are possible that will accommodate the light switching mechanism on the light path between the light source and the SLM 120. The SLM 121 is a mirror array with mirrors that have two states—an “on” state in which the light is reflected toward the SLM 120, and an “off” state in which the mirror reflects light toward second SLM beam dump 481. In this example all of the mirrors are switched as one. A discussion of most of the components of the tool in FIG. 30 can be found in the text relating to FIG. 4. Further explanation of the operation of the tool is given with reference to FIG. 31.

In FIG. 31, the timing of the switching of the SLMs 120 and 121 is shown by waveforms 3120 and 3121, respectively. When SLM 120 is in the “on” state, all of the elements of the SLM may be individually “on” or “off”, in other words an exposure pattern may be loaded on the SLM. When the SLM 120 is in the “off” state, all of the elements of the SLM are “off”. The same is true for SLM 121, except all of the elements of the SLM are “on” when SLM 121 is in the “on” state. SLMs 120 and 121 have the same time interval T between switching, in other words the same switching frequency; however, they are shifted out of phase by a time shift of $T(1-1/n)$. All elements of both SLMs are switched “off” every other time interval. Only when both SLMs are in the “on” state can light reach the substrate, which is for a time span T/n every other time interval. During this time span the projected image must move across the surface of the substrate a distance of one projected mirror pitch pM (which is the same as one pixel’s length on the substrate surface). This results in a stage speed v, given by the equation:

$$v=npMT \quad (7)$$

where n is a constant. The time between exposures of the substrate is 2T, during which time the pattern on the SLM 120 will have shifted by 2n rows. In principle n can have any value greater than 1; however, practical choices for n will typically be integers greater than one and less than 10.

FIG. 32 illustrates the shifting of patterns on the SLM and the corresponding image on the substrate. In this example, the substrate is on a stage and moves at constant speed in the

x direction during exposures. The following are shown, with reference also to FIG. 30: part of SLM 120, which is an array of elements 3200 with an area of 12 rows by 6 columns; a corresponding part of substrate 140, which is an array of pixels 3202 with an area of 4 rows by 6 columns; resultant image 3207 with projected row pitch (width of a pixel) 1008. The resultant image shows one possible latent image on the substrate due to completion of the entire series of exposures. "Snapshots" of the corresponding parts of the SLM and substrate are shown at equally spaced times T1 through T7, where the time interval is T (the times T1 through T5 are also labeled in the timing diagram, FIG. 31, for reference). The parts of the SLM and substrate are indicated in FIG. 32 by M and S, respectively. The SLM array 3200, the substrate array 3202 and the resultant image 3207 are drawn as if viewed from a position directly above them and looking down in the -z direction of stationary coordinate system 160. For ease of illustration, in each "snapshot" the SLM and substrate arrays are shown next to each other. The projected row pitch 1008 in the resultant image is the row pitch in the SLM array 3200 times the magnification of the projection lens system 430. However, for ease of illustration, in each "snapshot" the SLM and substrate arrays are shown having the same size and orientation. The grid shown on the arrays 3200 and 3202, and the image 3207 is for reference only. A light square in 3200 corresponds to an SLM element in the "on" state, while a dark square corresponds to one in the "off" state. The light and dark areas in 3202 correspond to the states of the SLM elements for that "snapshot". The example shown in FIG. 32 is for n=2. An exposure is made every 2T and the pattern on the SLM array is seen to have moved by 4 rows during this time period. The resultant image is the same as seen in FIG. 10, even though the substrate in FIG. 32 was moving twice as fast during exposure.

The approach described above with reference to FIGS. 30 through 32 is an example of how to increase the throughput of substrates, without having to reduce the switching time of the SLM. This is important when the minimum switching time for the SLM is already being used, since the throughput of substrates can still be increased. The cost of this increase in throughput is a more complex lithography tool, including a light switching mechanism and an SLM with a larger number of rows (to accommodate the movement of 2n rows between exposures).

Clearly, the tool of FIG. 30 can be used to implement gray level techniques, as described previously. The tool of FIG. 30 can be modified and operated in many ways, as described earlier for the tools of FIGS. 1 through 6. For example a variety of image movement mechanisms, as shown in FIGS. 2 and 3, can be integrated into the tool of FIG. 30.

The light switching mechanism 121 in FIG. 30 can clearly be effective in different positions, both in front of and beyond the SLM 120 on the light path, providing appropriate optical adjustments are made. The light switching mechanism may be integrated into the light source, and may even be an intrinsic property of the light source (for example a pulsed laser). The light switching mechanism can be a SLM, a shutter, a rotating mirror, or any other optical component capable of controlling the passage of light along the light path. Those skilled in the art will be aware of the many ways in which these light switching mechanisms can be incorporated and used in the many embodiments of the optical lithography tool of the invention. For example, the addition of some lenses between the SLM 121 and SLM 120 shown in FIG. 30 would allow an image of the pixels of SLM 121 to be focused, in one-to-one correspondence, onto the pixels

of SLM 120—this would allow the SLM 121 to be used to control the passage of light independently for different blocks of array elements or even to control the passage of light on an individual element basis.

Now to consider the case in which the light switching mechanism can be switched faster than the SLM 120. In FIG. 33, the timing of the switching of the SLM 120 and the light switching mechanism is shown by waveforms 3320 and 3321, respectively. When SLM 120 is in the "on" state, all of the elements of the SLM may be individually "on" or "off", in other words an exposure pattern may be loaded on the SLM. When the SLM 120 is in the "off" state, all of the elements of the SLM are "off". The pattern on the SLM can be switched every time interval T. The light switching mechanism is configured as a simple two state "on/off" switch. Only when both the SLM and the light switching mechanism are in the "on" state can light reach the substrate. The light switching mechanism provides the limiting time span T/n during which light can reach the substrate. During this time span the projected image must move across the surface of the substrate a distance of one projected mirror pitch pM (which is the same as one pixel's length on the substrate surface). This results in a stage speed v, given by equation (7). The time between exposures of the substrate is T, during which time the pattern on the SLM 120 will have shifted by n rows. In principle n can have any value greater than 1; however, practical choices for n will typically be integers greater than one and less than 20, in which case the time span will be a submultiple of said switching time interval.

FIG. 34 shows an optical lithography tool with optics configured to allow the projected images from two SLM area arrays, 3420 and 3421, to overlap on the surface of a substrate. If desired, the overlapping images may be brought into register—superimposed exactly, pixel for pixel. A light source 110 and prisms 3410 through 3413 provide illumination to two SLM area arrays 3420 and 3421. The light reflected from the SLM area arrays is combined by prisms 3410 through 3413 and then projected by imaging optics 3430 onto the photosensitive surface of a substrate 140. The substrate 140 is carried by a stage 150 which moves the substrate in the x-y plane of coordinate axes 160. The optical configuration of FIG. 34 may be modified to include more SLM area arrays. An example of an optical configuration allowing for the projected images of three SLM area arrays to overlap on the surface of a substrate is shown in U.S. Pat. No. 6,582,080 to Gibbon et al., incorporated by reference herein. Those skilled in the art will appreciate that the tool shown in FIG. 34 may be modified along the lines of the apparatus shown in FIGS. 1 through 6, thus providing many further embodiments of the invention. The apparatus of FIG. 34 can be operated in a similar manner to that of FIG. 30. Further explanation of the operation of the tool is given with reference to FIG. 35.

In FIG. 35, the timing of the switching of the area arrays 3420 and 3421 is shown by waveforms 3520 and 3521, respectively. When array 3420 is in the "on" state, all of the elements of the array may be individually "on" or "off", in other words an exposure pattern may be loaded on the array. When the array 3420 is in the "off" state, all of the elements of the array are "off". The same is true for array 3421. Arrays 3420 and 3421 have the same time interval T between switching, in other words the same switching frequency; however, they are shifted out of phase by a time shift of T(1-1/n). All elements of both arrays are switched "off" every other time interval. Both area arrays are in the "on" state and a double dose of light reaches the substrate for a

time span T/n every other time interval. During this time span the projected image must move across the surface of the substrate a distance of one projected mirror pitch pM (which is the same as one pixel's length on the substrate surface). This results in a stage speed v , given by equation (7). The time between double dose exposures of the substrate is $2T$, during which time the pattern on the SLM 120 will have shifted by $2n$ rows. Adjustment of the dose and development conditions of the photosensitive surface of the substrate are made to ensure that only pixels which have received sufficient double dose exposures will form the developed pattern.

Clearly, the tool of FIG. 34 can be used to implement gray level techniques, as described previously. The tool of FIG. 34 can be modified and operated in many ways, as described earlier for the tools of FIGS. 1 through 6 and 30. For example a variety of image movement mechanisms, as shown in FIGS. 2 and 3, can be integrated into the tool of FIG. 34.

An alternative mode of operation for the optical lithography tool of FIG. 34 is to have the area arrays 3420 and 3421 operating in phase. In this case the speed of the substrate will be limited by equation (1). This mode of operation may be useful when a single area array is unable to deliver a large enough dose per unit time.

Referring to the description of FIGS. 8 and 9, an SLM area array is oriented in such a way that the columns of pixels in the projected image on the substrate are parallel to the direction of movement of the image itself. This results in blurring of the edges of the pixels which are orthogonal to the direction of movement; however, the edges parallel to the direction of movement are not blurred by the movement. In order to implement gray level techniques, the edges parallel to the direction of movement must also be blurred. Blurring of the parallel edges can be achieved in many ways as described earlier, all of which involve projecting a blurred image of the SLM onto the substrate surface. There is an alternative approach to achieving blurred edges which can be used with all of the embodiments of the optical lithography tool disclosed above—the SLM area array is oriented in such a way that the columns of pixels in the projected image on the substrate are not parallel to the direction of movement of the image itself. For example, the columns in the projected image may be at an angle of 45 degrees to the direction of movement, in which case all of the edges of the square pixels will be equally blurred due to the movement alone.

While the invention has been described with reference to particular embodiments, this description is solely for the purpose of illustration and is not to be construed as limiting the scope of the invention claimed below.

What is claimed is:

1. A lithographic method, comprising the steps of:
 illuminating a spatial light modulator, said spatial light modulator comprising an area array of individually switchable elements;
 projecting an image of said spatial light modulator on a photosensitive surface of a substrate;
 moving said image across said surface of said substrate; while said image is moving, switching said elements of said spatial light modulator, whereby a pixel on said photosensitive surface receives, in serial, doses of energy from multiple elements of said spatial light modulator, thus forming a latent image on said surface; and
 blurring said image, where said blurring enables sub-pixel resolution feature edge placement.

2. A lithographic method as in claim 1, wherein said blurring comprises defocusing said image.

3. A lithographic method as in claim 1, wherein said blurring is implemented by a diffuser positioned between said spatial light modulator and said substrate.

4. A lithographic method as in claim 1, wherein said blurring comprises adjusting the numerical aperture of projection optics positioned between said spatial light modulator and said substrate.

5. A lithographic method as in claim 1, wherein said blurring is implemented by a microlens array positioned between said spatial light modulator and said substrate.

6. A lithographic method as in claim 1, wherein said illuminating step comprises continuously illuminating said spatial light modulator.

7. A lithographic method as in claim 1, wherein said illuminating step is implemented by a lamp system comprising an arc lamp.

8. A lithographic method as in claim 1, wherein said illuminating step is implemented by a laser.

9. A lithographic method as in claim 8, wherein said laser is a continuous laser.

10. A lithographic method as in claim 8, wherein said laser is a quasi-continuous laser.

11. A lithographic method as in claim 1, wherein, during formation of said latent image, said projecting step comprises continuously projecting said image of said spatial light modulator on said photosensitive surface of said substrate.

12. A lithographic method as in claim 1, wherein said projecting step is implemented by a telecentric projection lens system.

13. A lithographic method as in claim 1, wherein said spatial light modulator comprises a digital micro-mirror device.

14. A lithographic method as in claim 1, wherein said moving step is implemented by a stage.

15. A lithographic method as in claim 14, wherein said spatial light modulator is carried on said stage.

16. A lithographic method as in claim 15, wherein projection optics is carried on said stage.

17. A lithographic method as in claim 14, wherein said substrate is carried on said stage.

18. A lithographic method as in claim 1, wherein said substrate is a flexible film substrate.

19. A lithographic method as in claim 18, wherein said moving step is implemented by rotatable, spaced apart, axially parallel film drums, said flexible film substrate being wrapped around and tensioned between said drums.

20. A lithographic method as in claim 18, wherein said moving step is further implemented by a stage, said spatial light modulator being carried on said stage.

21. A lithographic method as in claim 20, wherein projection optics is carried on said stage.

22. A lithographic method as in claim 20, wherein said stage and said substrate move in orthogonal directions to each other.

23. A lithographic method for a substrate, comprising the steps of:

positioning a substrate below a spatial light modulator;
 illuminating said spatial light modulator, said spatial light modulator being positioned on a stage, said stage being controlled to move in a patterning direction during exposure of said substrate, said spatial light modulator comprising an area array of individually switchable elements, said elements having pitch p , as measured in said patterning direction;

27

moving said spatial light modulator in said patterning direction at speed v over said substrate;
 while said spatial light modulator is moving, continuously projecting a blurred image of said spatial light modulator on said substrate; and
 while said blurred image is being projected, switching said spatial light modulator at times separated by a time interval

$$T=p/v$$

such that a pixel on a photosensitive surface of said substrate receives, in serial, doses of energy from multiple elements of said spatial light modulator, where said blurred image enables sub-pixel resolution feature edge placement.

24. A lithographic method for a flexible film substrate, comprising the steps of:

moving said flexible film substrate in a patterning direction at speed v ;
 continuously illuminating a spatial light modulator, said spatial light modulator comprising an area array of individually switchable elements, said elements having pitch p , as measured in said patterning direction;
 while said flexible film substrate is moving, illuminating said substrate with an image, at magnification M , of said continuously illuminated spatial light modulator; and
 while said substrate is being illuminated, switching said spatial light modulator at times separated by a time interval

$$T=pM/v$$

such that a pixel on a photosensitive surface of said substrate receives, in serial, doses of energy from multiple elements of said spatial light modulator;

wherein said moving of said substrate is implemented by rotatable, spaced apart, axially parallel film drums, said substrate being wound around and tensioned between said drums.

25. A lithographic method as in claim 24, wherein said image, at magnification M , of said continuously illuminated spatial light modulator is blurred.

26. A lithographic method, comprising the steps of:

- (a) positioning a substrate below a spatial light modulator;
- (b) illuminating said spatial light modulator, said spatial light modulator comprising an area array of individually switchable elements;
- (c) projecting a blurred image, at magnification M , of said spatial light modulator on a photosensitive surface of said substrate;
- (d) moving said image in a patterning direction at speed v across said photosensitive surface;
- (e) while said image is moving, switching said spatial light modulator after a time interval of

$$T=pM/v$$

where p is the pitch of said elements, as measured in said patterning direction; and

(f) repeating step (e), such that pixels on said substrate receive, in serial, doses of energy from multiple elements of said spatial light modulator, until a desired latent image is formed on said photosensitive surface.

27. A lithographic method, comprising the steps of:

illuminating a spatial light modulator using a light source, said spatial light modulator comprising an area array of individually switchable elements;
 projecting an image of said spatial light modulator on a photosensitive surface of a substrate;

28

moving said image across said surface of said substrate; while said image is moving, switching said elements of said spatial light modulator at times separated by a time interval;

controlling passage of light along a light path, said light path going from said light source to said spatial light modulator and ending at said substrate; and
 blurring said image, where said blurring enables sub-pixel resolution feature edge placement.

28. A lithographic method as in claim 27, wherein passage of light is controlled by a light switching mechanism, said mechanism being operated at the same frequency as, and out of phase with, said elements of said spatial light modulator.

29. A lithographic method as in claim 28, wherein all of said elements of said spatial light modulator are in an off state every other time interval and said switching mechanism is in an off state every other time interval.

30. A lithographic method as in claim 27, wherein passage of light is allowed for a time span which is a fraction of said switching time interval, said image moving a single pixel's length on said substrate surface during said time span.

31. A lithographic method as in claim 30, wherein said time span is a submultiple of said switching time interval.

32. A lithographic method, comprising the steps of:

illuminating a spatial light modulator using a light source, said spatial light modulator comprising an area array of individually switchable elements;

projecting an image of said spatial light modulator on a photosensitive surface of a substrate;

moving said image across said surface of said substrate; while said image is moving, switching said elements of said spatial light modulator at times separated by a time interval; and

controlling passage of light along a light path, said light path going from said light source to said spatial light modulator and ending at said substrate;

wherein passage of light is controlled by a light switching mechanism, said mechanism being operated at the same frequency as, and out of phase with, said elements of said spatial light modulator.

33. A lithographic method as in claim 32, wherein all of said elements of said spatial light modulator are in an off state every other time interval and said switching mechanism is in an off state every other time interval.

34. A lithographic method, comprising the steps of:

illuminating a spatial light modulator using a light source, said spatial light modulator comprising an area array of individually switchable elements;

projecting an image of said spatial light modulator on a photosensitive surface of a substrate;

moving said image across said surface of said substrate; while said image is moving, switching said elements of said spatial light modulator at times separated by a time interval; and

controlling passage of light along a light path, said light path going from said light source to said spatial light modulator and ending at said substrate;

wherein passage of light is allowed for a time span which is a fraction of said switching time interval, said image moving a single pixel's length on said substrate surface during said time span.

35. A lithographic method as in claim 34, wherein said time span is a submultiple of said switching time interval.

29

36. A lithographic method, comprising the steps of:
illuminating a plurality of spatial light modulators using a light source, each of said plurality of spatial light modulators comprising an area array of individually switchable elements;

projecting images of each of said plurality of spatial light modulators on a photosensitive surface of a substrate; moving said images across said surface of said substrate; and

while said images are moving, switching said elements of said plurality of spatial light modulators, whereby a pixel on said photosensitive surface receives, in serial, doses of energy from multiple elements of said plurality of spatial light modulators, thus forming a latent image on said surface; and

blurring said images, where said blurring enables sub-pixel resolution feature edge placement; wherein at least two of said projected images simultaneously overlap on said substrate.

37. A lithographic method as in claim 36, wherein said spatial light modulators with overlapping projected images on said substrate are switched with the same frequency and are switched out of phase with each other.

38. A lithographic method as in claim 36, wherein said overlapping projected images are in register.

39. A lithographic method, comprising the steps of:

(a) positioning a substrate below a spatial light modulator;
(b) illuminating said spatial light modulator, said spatial light modulator comprising an area array of individually switchable elements;

(c) projecting an image, at magnification M, of said spatial light modulator on a photosensitive surface of said substrate;

(d) switching said elements of said spatial light modulator at times separated by a time interval T;

(e) while said elements are switching, moving said image in a patterning direction across said photosensitive surface at speed

$$v=npM/T$$

where p is the pitch of said elements, as measured in said patterning direction, and n is an integer; and

(f) controlling passage of light along a light path, said light path going from said light source to said spatial light modulator and ending at said substrate, where passage of light is controlled by a light switching mechanism, said mechanism being operated at the same frequency as said elements of said spatial light modulator and shifted out of phase with said elements of said spatial light modulator by a time shift $T(1-1/n)$.

40. A lithographic method as in claim 39, whereby pixels on said substrate receive, in serial, doses of energy from multiple elements of said spatial light modulator, until a desired latent image is formed on said photosensitive surface.

41. A lithographic method as in claim 39, further comprising blurring said image of said spatial light modulator.

42. A lithographic method as in claim 39, wherein all of said elements of said spatial light modulator are in an off state every other time interval and said switching mechanism is in an off state every other time interval.

43. A lithographic method, comprising the steps of:

(a) positioning a substrate below a spatial light modulator;
(b) illuminating said spatial light modulator, said spatial light modulator comprising an area array of individually switchable elements;

(c) projecting an image, at magnification M, of said spatial light modulator on a photosensitive surface of said substrate;

30

(d) switching said elements of said spatial light modulator at times separated by a time interval T;

(e) while said elements are switching, moving said image in a patterning direction across said photosensitive surface at speed

$$v=npM/T$$

where p is the pitch of said elements, as measured in said patterning direction, and n is a constant; and

(f) controlling passage of light along a light path, said light path going from said light source to said spatial light modulator and ending at said substrate, where passage of light is controlled by a light switching mechanism, said mechanism being operated to allow the passage of light for a time span T/n.

44. A lithographic method as in claim 43, further comprising repeating step (f), whereby pixels on said substrate receive, in serial, doses of energy from multiple elements of said spatial light modulator, until a desired latent image is formed on said photosensitive surface.

45. A lithographic method as in claim 43, further comprising blurring said image of said spatial light modulator.

46. A lithographic method as in claim 43, wherein said light switching mechanism is operated to allow the passage of light for one time span T/n per time interval T.

47. A lithographic method as in claim 43, wherein n is an integer.

48. A lithographic method, comprising the steps of:

illuminating a spatial light modulator using a light source, said spatial light modulator comprising an area array of individually switchable elements;

projecting an image of said spatial light modulator on a photosensitive surface of a substrate;

moving said image across said surface of said substrate; while said image is moving, switching said elements of said spatial light modulator; and

blurring said image, where said blurring enables sub-pixel resolution feature edge placement;

wherein the direction of movement of said image is not parallel to columns of pixels in said projected image of said spatial light modulator.

49. A lithographic method as in claim 48 wherein said elements of said spatial light modulator are switched at times separated by a time interval, whereby pixels on said substrate receive, in serial, doses of energy from multiple elements of said spatial light modulator, until a desired latent image is formed on said photosensitive surface.

50. A lithographic method as in claim 1, wherein said individually switchable elements are configured in rows and the direction of movement of said image across the surface of said substrate is perpendicular to said rows of elements.

51. A lithographic method as in claim 1, wherein said moving step includes moving said image across said surface of said substrate in a serpentine manner.

52. A lithographic method, comprising the steps of:

illuminating a plurality of spatial light modulators, each of said plurality of spatial light modulators comprising an area array of individually switchable elements;

projecting an image of said plurality of spatial light modulators on a photosensitive surface of a substrate;

moving said image across said surface of said substrate; while said image is moving, switching said elements of said plurality of spatial light modulators, whereby a pixel on said photosensitive surface receives, in serial, doses of energy from multiple elements of said plurality of spatial light modulators, thus forming a latent image on said surface; and

blurring said image, where said blurring enables sub-pixel resolution feature edge placement.

blurring said image, where said blurring enables sub-pixel resolution feature edge placement.

blurring said image, where said blurring enables sub-pixel resolution feature edge placement.

31

53. A lithographic method as in claim 52, wherein each of said spatial light modulators exposes a swath of said photosensitive surface.

54. A lithographic method as in claim 52, wherein each of said spatial light modulators exposes a non-overlapping swath of said photosensitive surface.

55. A lithographic method as in claim 52, wherein said plurality of spatial light modulators are arranged in at least one row, said at least one row being perpendicular to the direction of movement of said image across the surface of said substrate.

56. A lithographic method as in claim 52, wherein said projecting step is implemented by a single projection lens system.

57. A lithographic method as in claim 52, wherein said projecting step is implemented by a multiplicity of projection lens systems.

58. A lithographic method as in claim 57, wherein said multiplicity of projection lens systems comprises a single projection lens system for each of said plurality of spatial light modulators.

32

59. A lithographic method as in claim 52, whereby a pixel on a photosensitive surface of said substrate receives, in serial, doses of energy from multiple elements of one of said plurality of spatial light modulators, thus forming a latent image on said surface.

60. A lithographic method as in claim 52, wherein said projecting step continuously projects an image of said plurality of spatial light modulators on a photosensitive surface of a substrate.

61. A lithographic method as in claim 24, wherein said second illuminating step continuously illuminates said substrate with an image, at magnification M , of said continuously illuminated spatial light modulator.

62. A lithographic method as in claim 26, wherein said projecting step continuously projects a blurred image, at magnification M , of said spatial light modulator on a photosensitive surface of said substrate.
